

## ABSTRACT

1  
2 A method and apparatus for implementing magnetostrictive sensor techniques for the  
3 nondestructive evaluation of pipes or tubes. A magnetostrictive sensor generates guided waves  
4 in a pipe or tube, which waves travel therethrough in a direction parallel to the longitudinal axis  
5 of the pipe or tube. This is achieved by using a magnetized ferromagnetic strip being pressed  
6 circumferentially against the pipe or tube. For improved efficiency, the strip may be made from  
7 an iron-cobalt alloy. The guided waves are generated in the strip and coupled to the pipe or tube  
8 and propagate along the length of said pipe or tube. For detection, the guided waves in the pipe  
9 or tube are coupled to the thin ferromagnetic strip and are detected by receiving MsS coils.  
10 Reflected guided waves may represent defects in the pipe or tube.
